

Design of Vertical Separation Schemes for the CEBAF 12 GeV Upgrade Extraction Lines

Due to the large horizontal beam size in higher passes of the upgraded 12 GeV CEBAF, a vertical extraction scheme is conceived to circumvent this problem. This note summarizes efforts carried out so far to prototype such a scenario in the 4th and 5th passes.

The vertical separation scheme consists of vertically separating RF separators, followed by a Lambertson magnet at the point of maximal vertical separation (E02, which is traditionally the horizontal separation point), where vertically separated extraction beam is diverted to the extraction channel and further down to a YR septum, and then brought back to the main linac axis via the BP-BQ chicane similar to the 6 GeV configuration. The recirculated beam does not receive a kick from the Lambertson and is brought back on axis through orbit correction. A main departure from 6 GeV extraction optics is in the polarity of the 3 extraction quads (E01-03). In the current case both E01 and E02 are vertically defocusing, and E03 is vertically focusing. This is seen not to introduce any disadvantage to the extraction optics, while much better matched to the Arc for the recirculated optics.

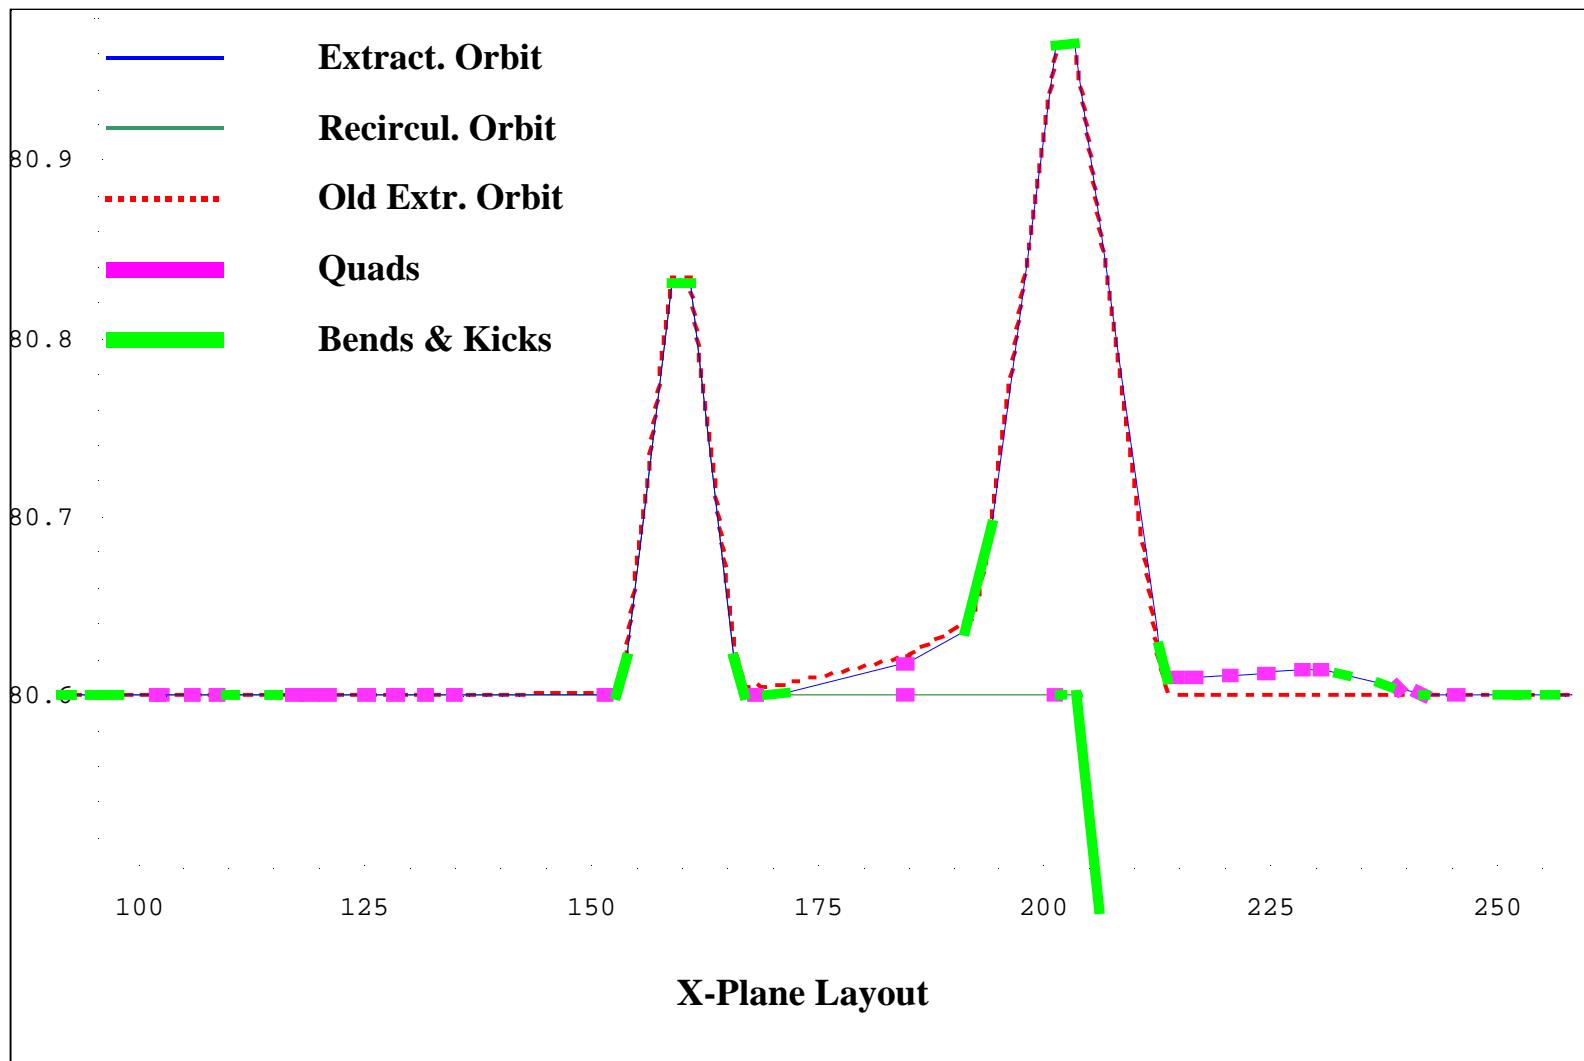

4th Pass:

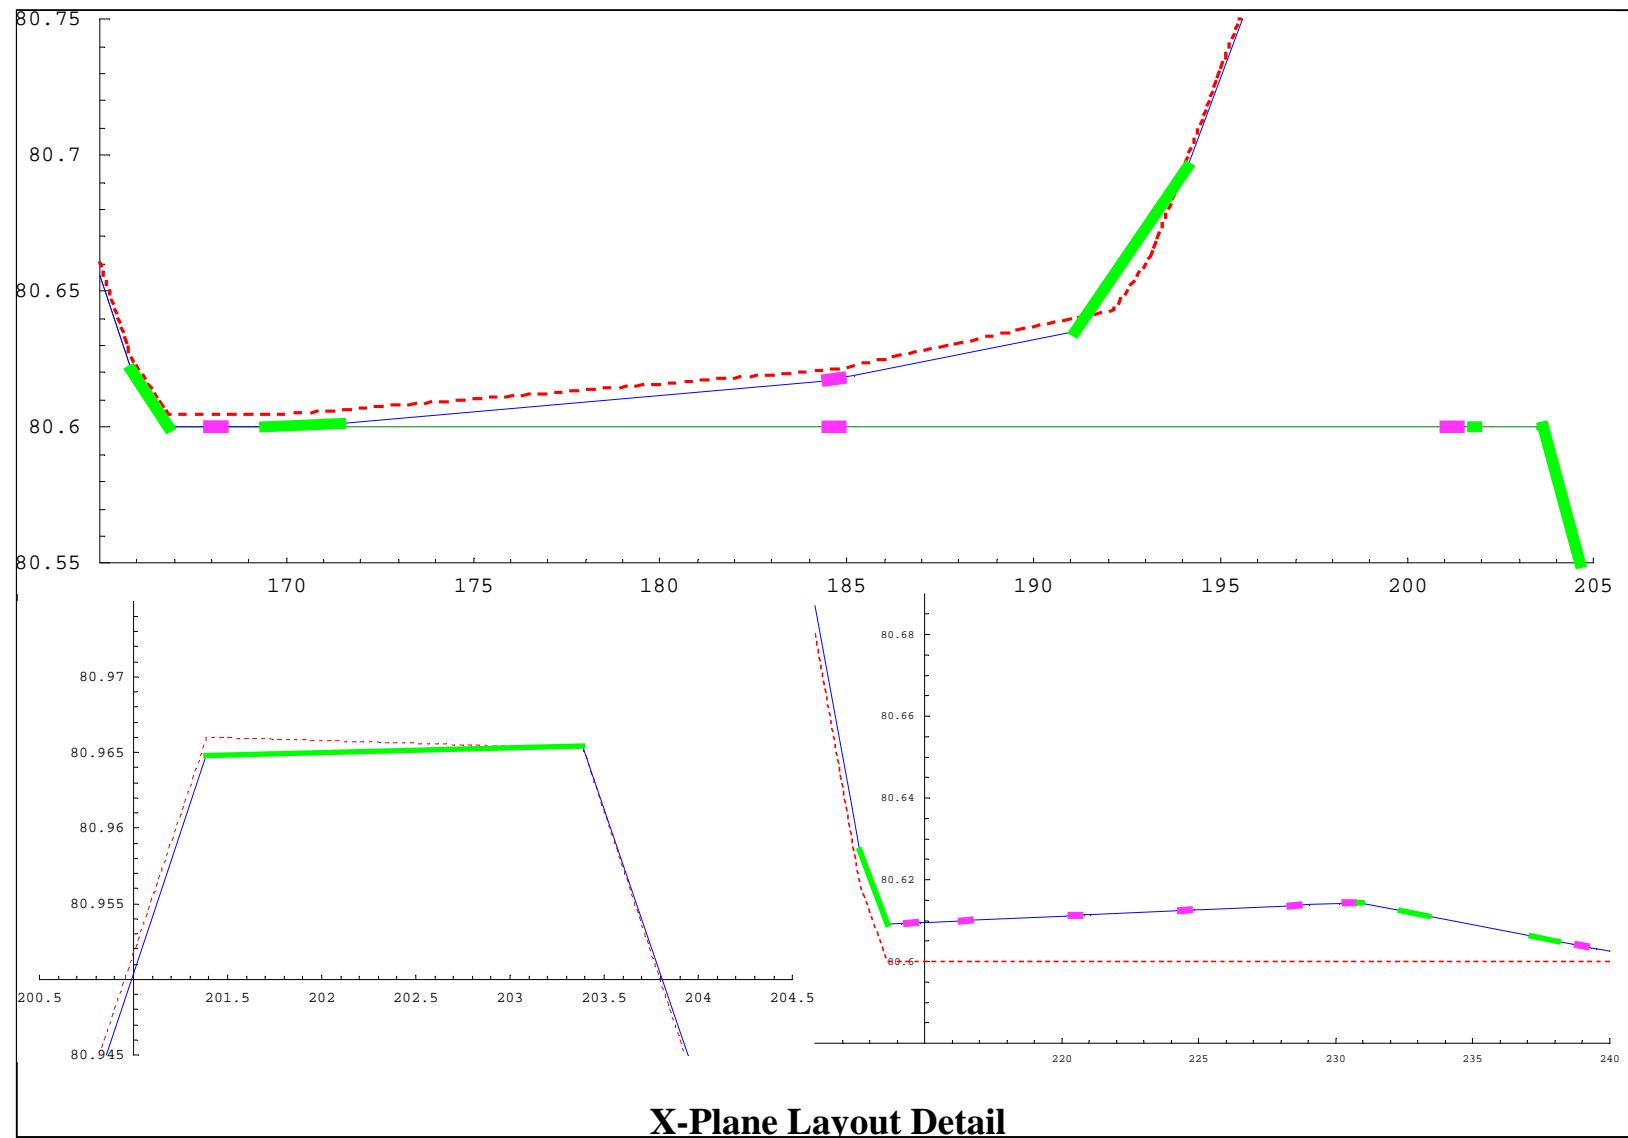

Study has been made with the RF separators operating at 48% and 60% of their full design gradients. In the latter case reduction in Lambertson & YR strengths can be attained. Beam line geometry and Twiss parameters for both extracted and recirculated beams are shown in the following pages. Nominal magnet strengths and beam separation in critical elements are also given.

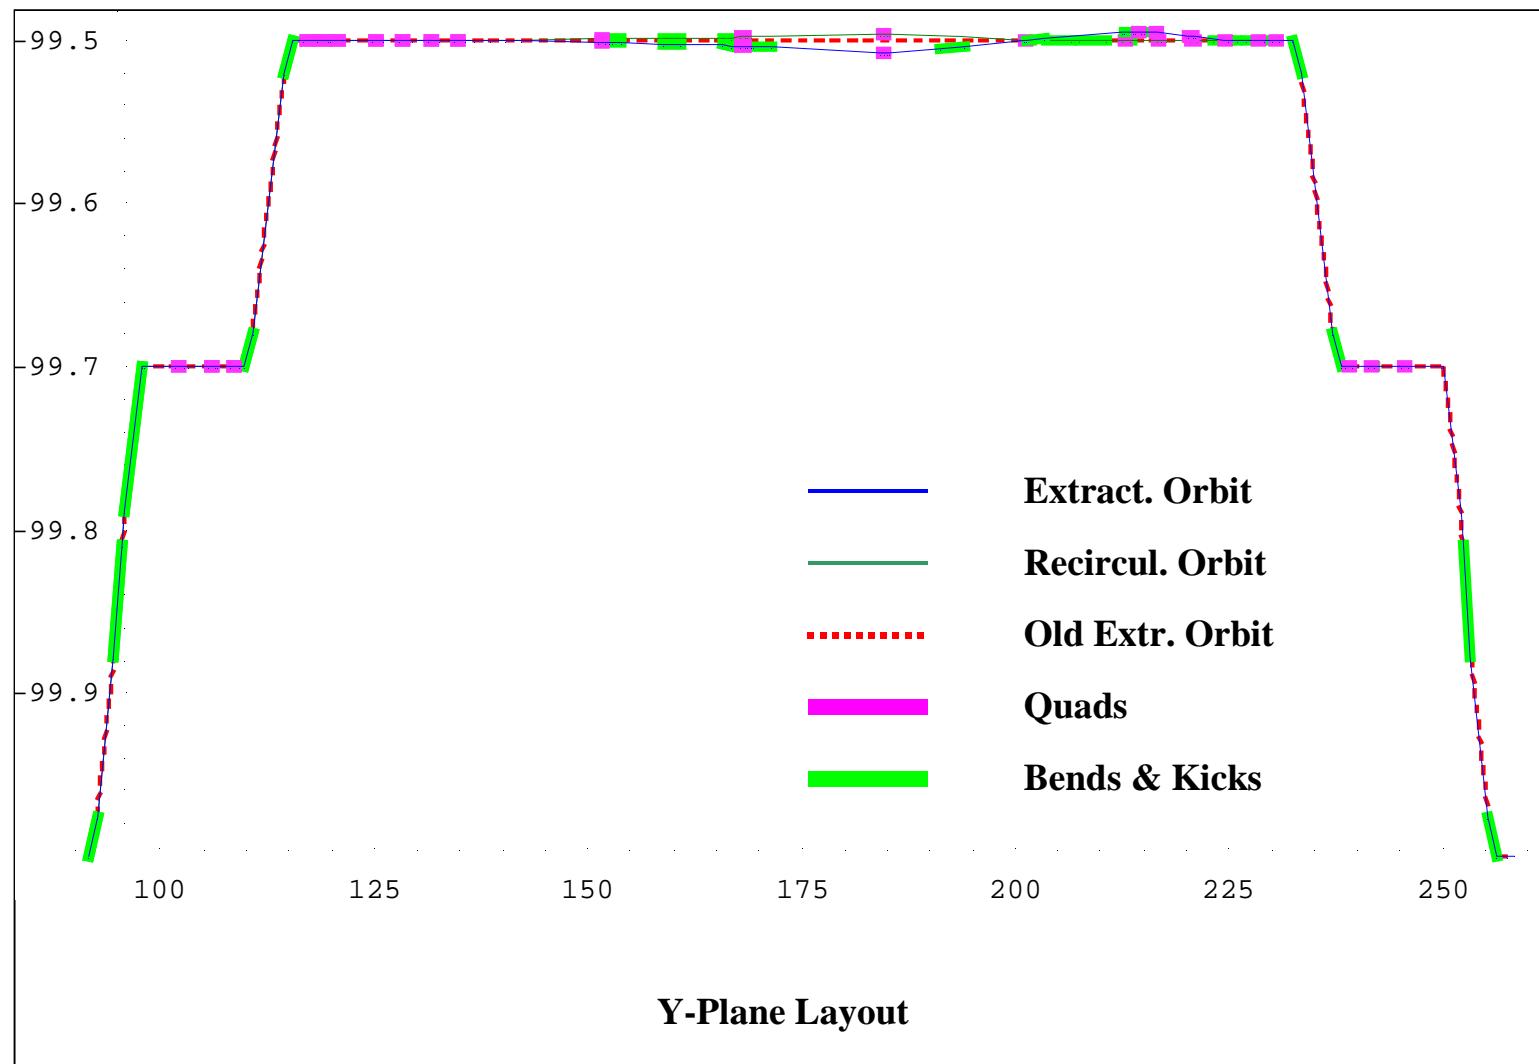

5th Pass:

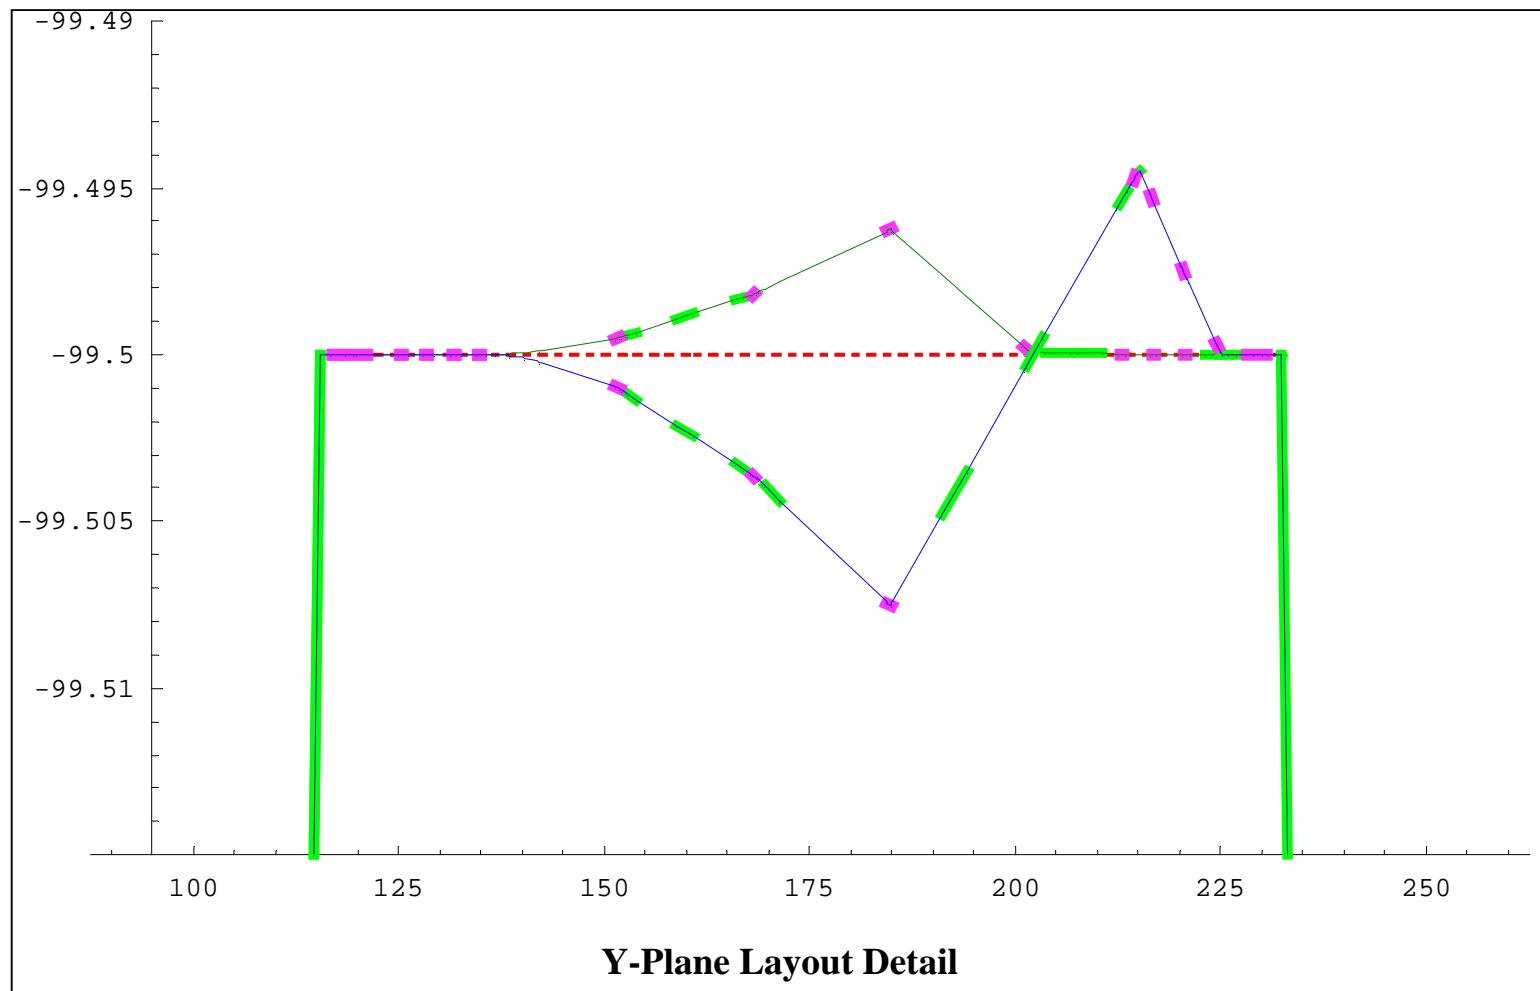

At this point only extracted beam line geometry has been completed. This is shown in the last page.

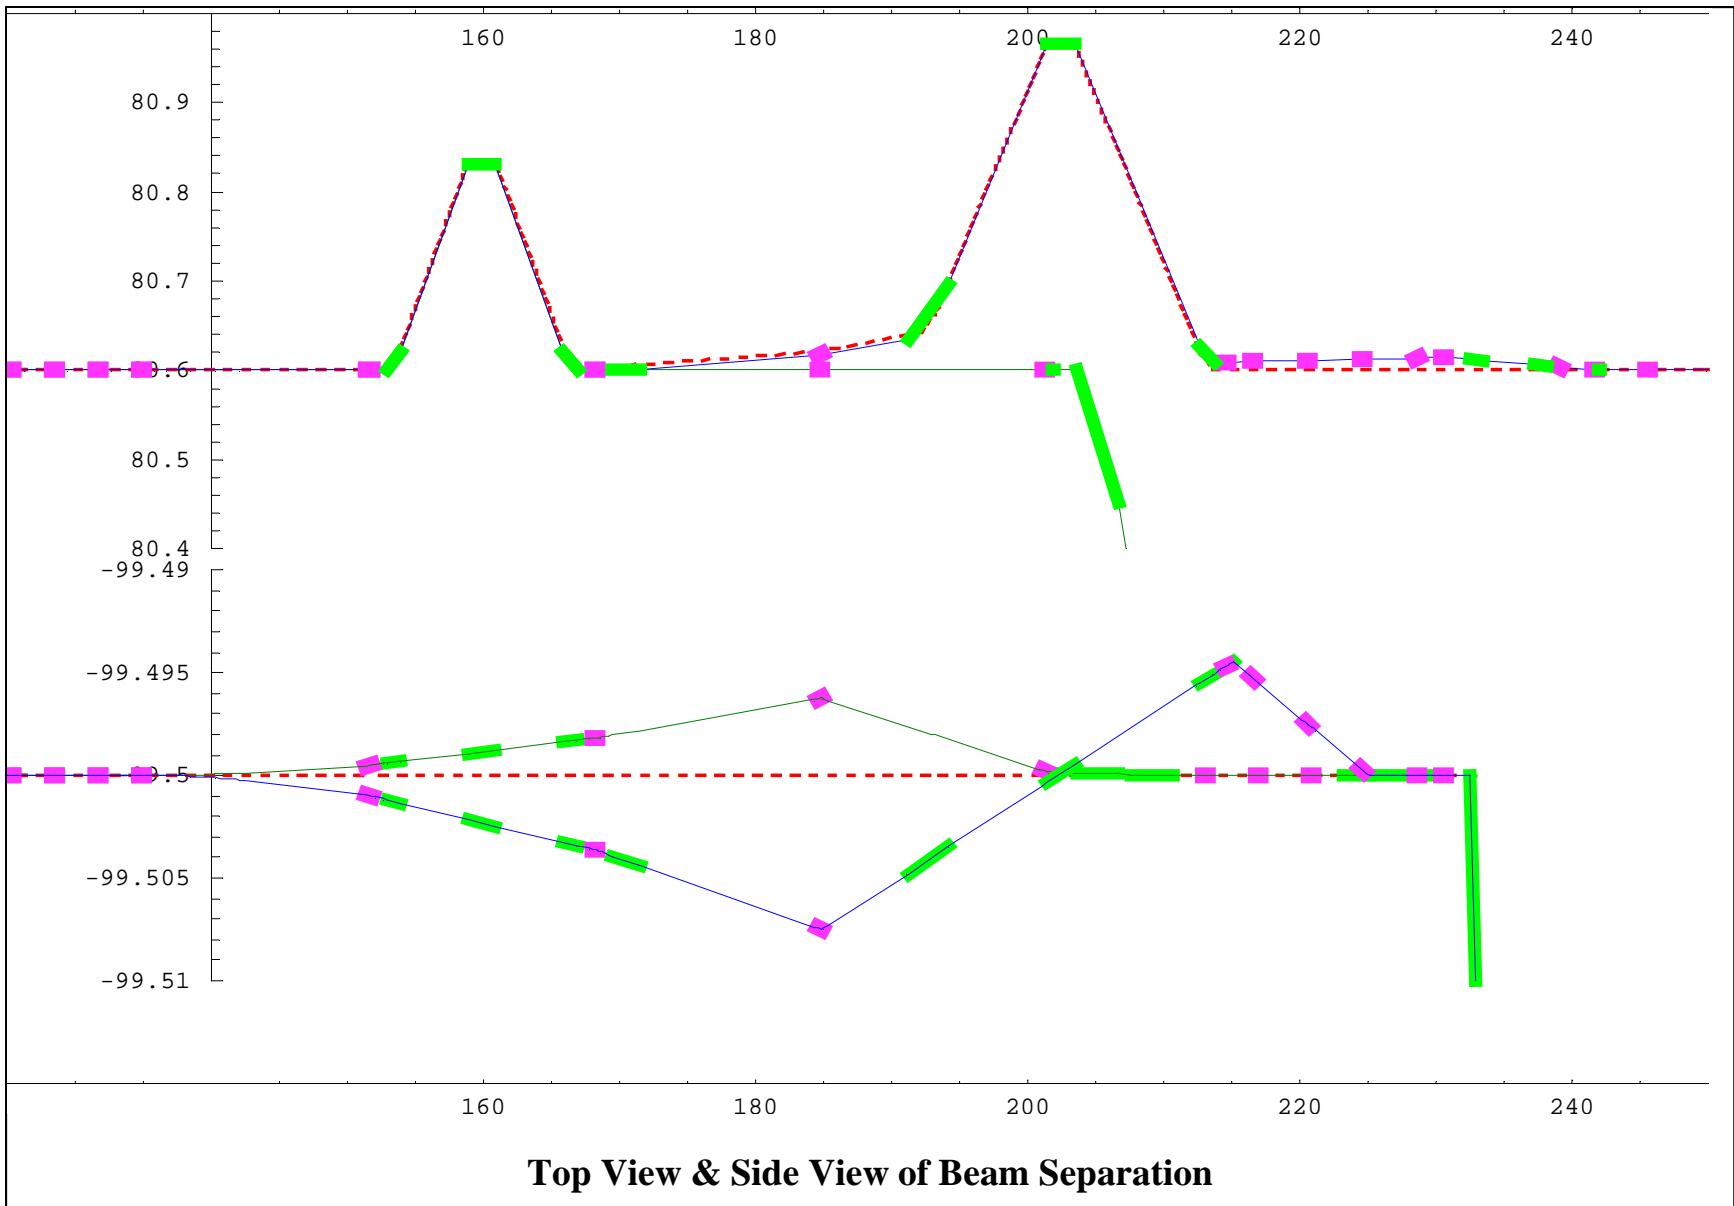

Pass 4 Extraction Layout

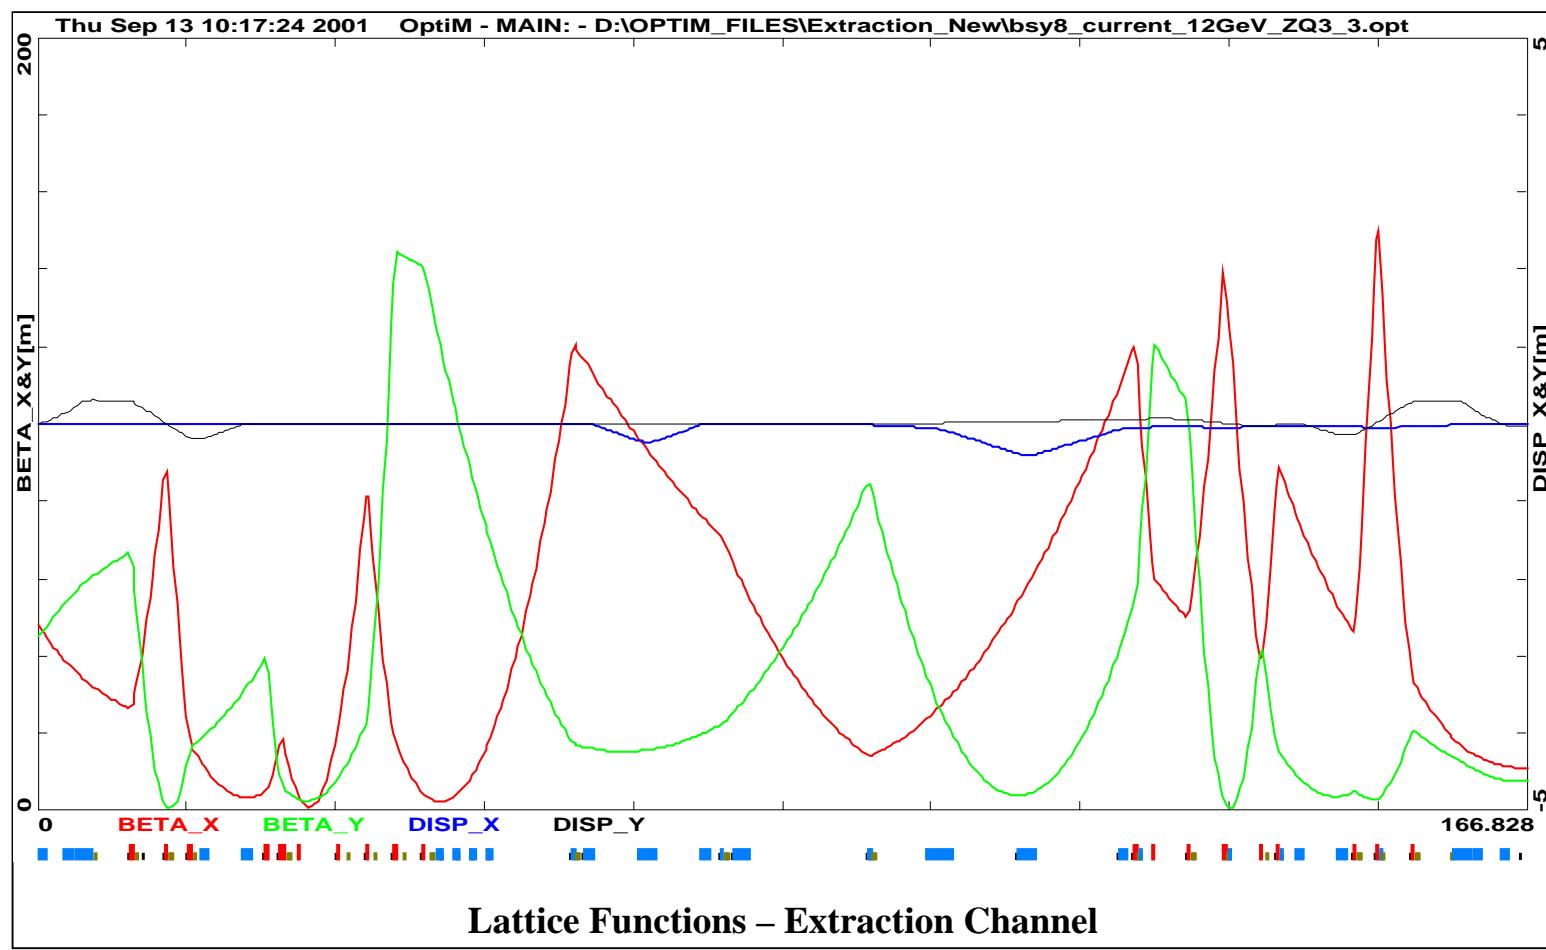

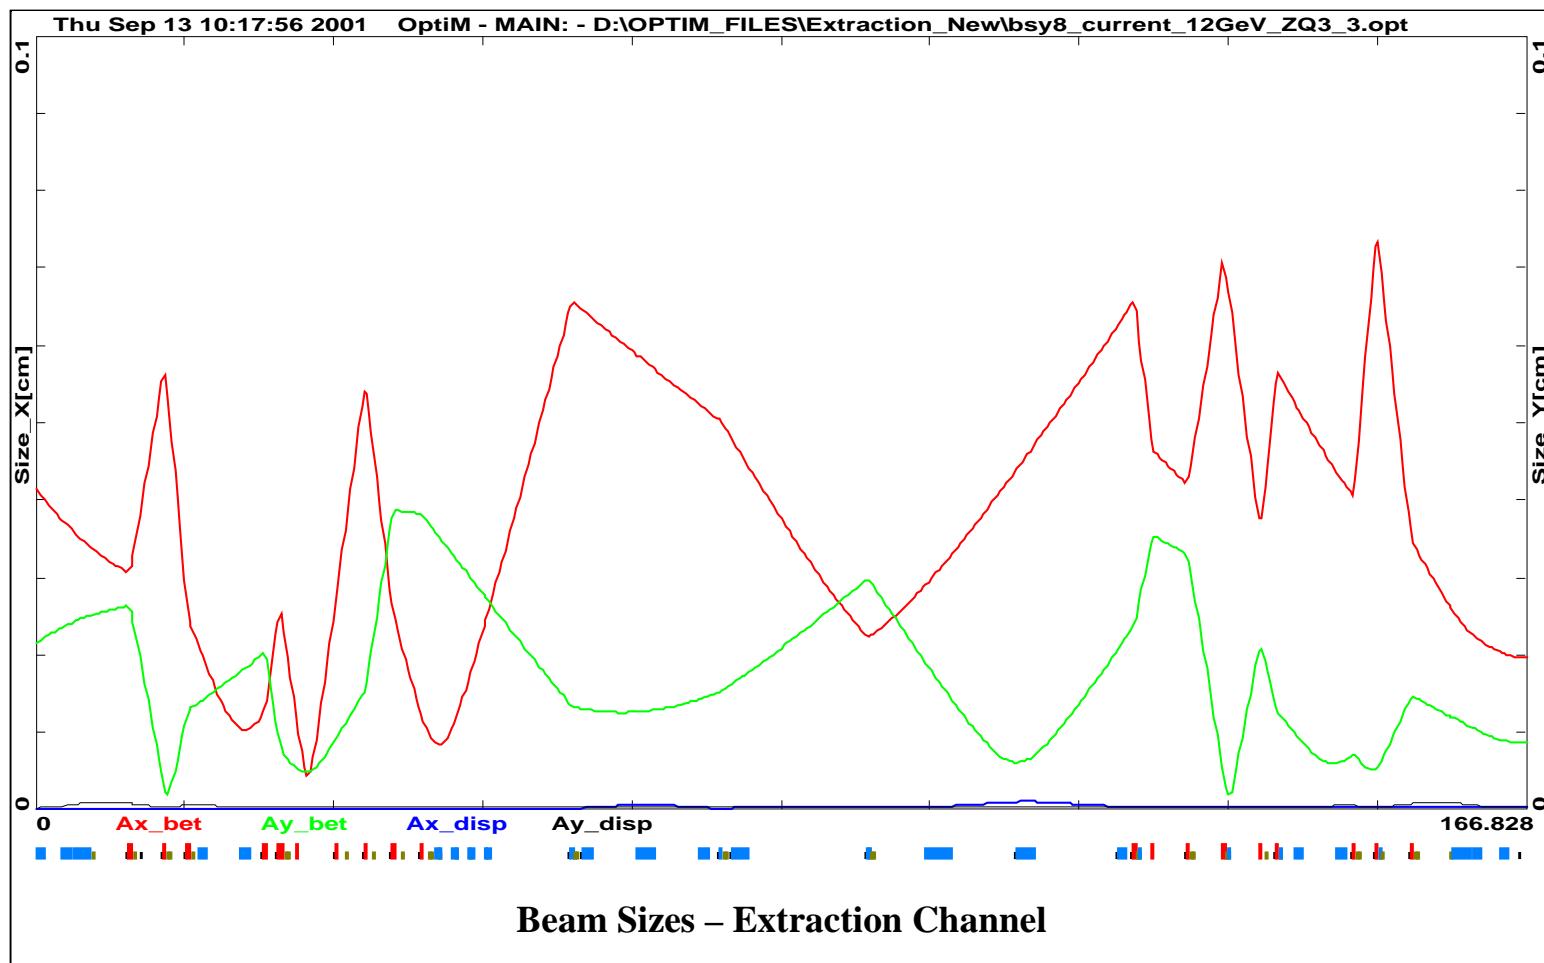

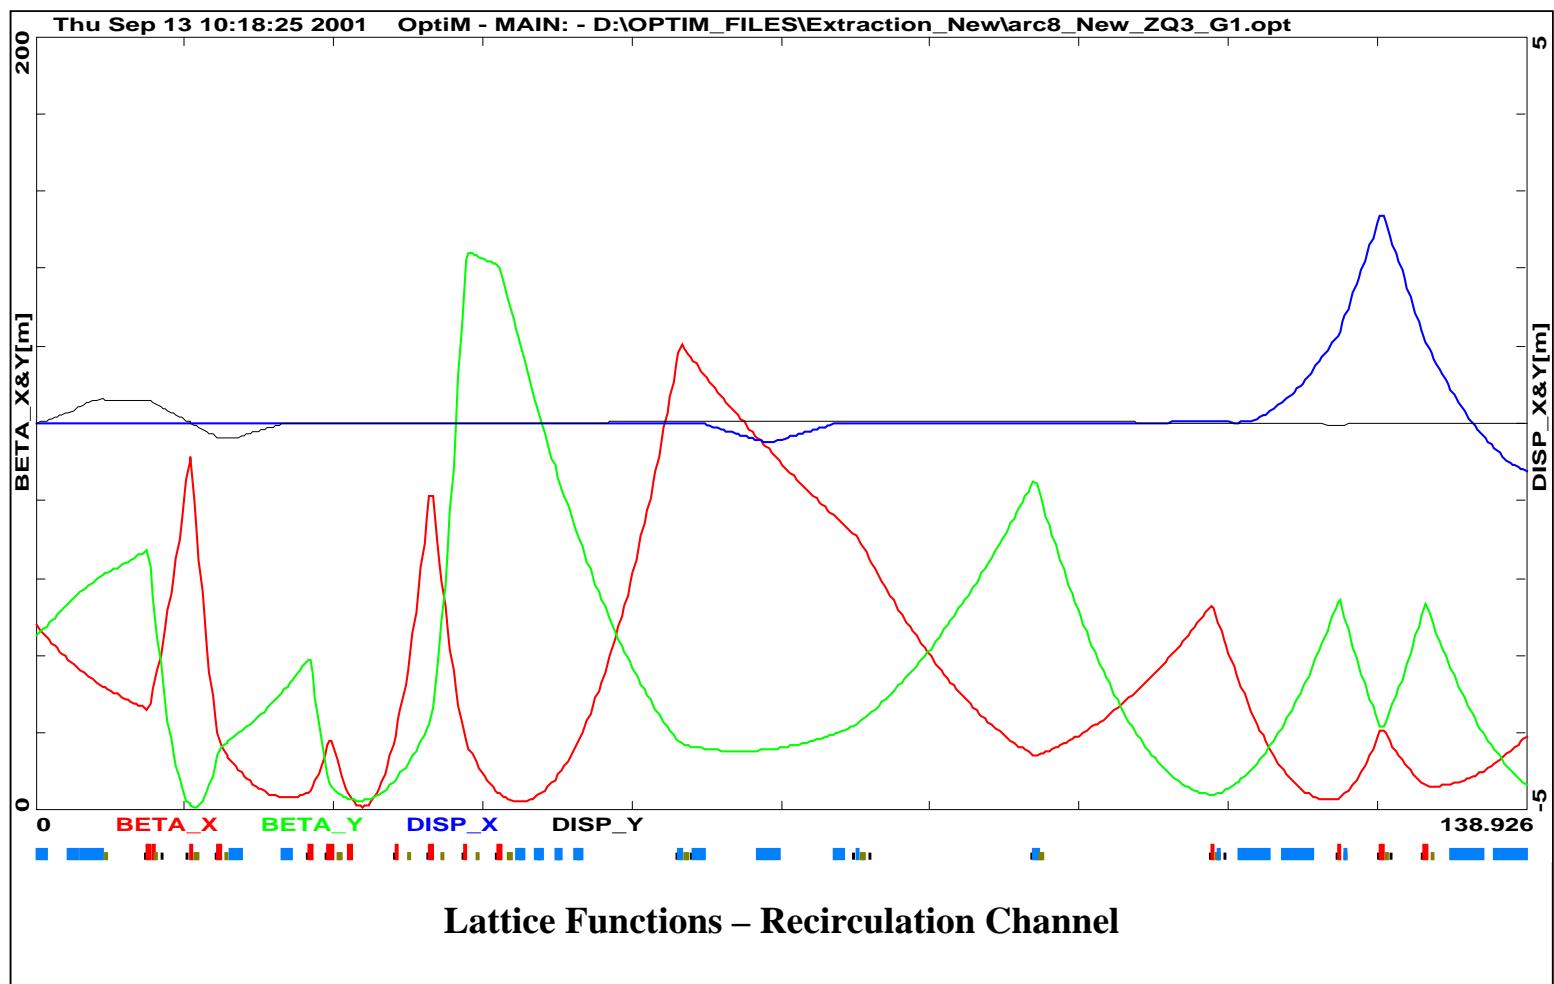

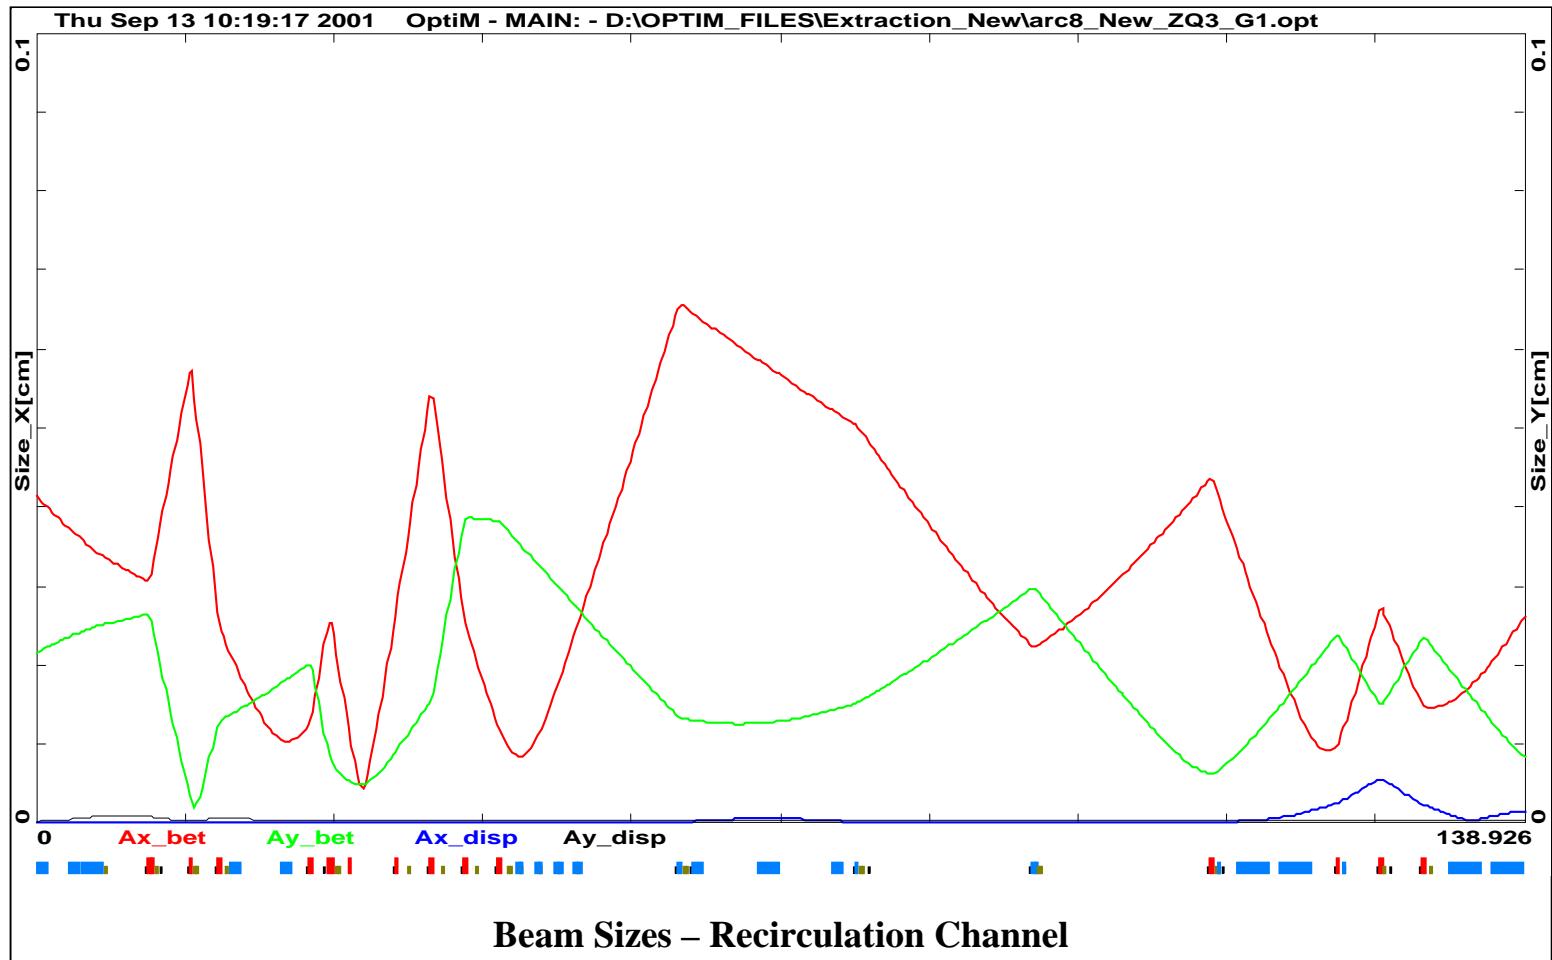

Beam Offset & Separation (All numbers in cm)

Baseline:

Location	X-Separation	Y-Separation	Offset (Recirc.)	Offset (Extrac.)
